There are two types of nuclear reactions: Fission, where a nucleus breaks into two or more pieces, and fusion where two or more nuclei combine to form a new element. In nuclear reactions, only the nucleus is involved. Electrons are ignored. Some atomic nuclei are inherently unstable and spontaneously change or "decay". There are four types of decay:

| Type | Symbol | Charge of <br> particle | Mass(AMU) | Effect on <br> Atomic \# | Effect on Atomic <br> Mass | Strength |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Alpha | $\alpha$ | $+2(H e$ <br> nucleus) | 4 | decrease by 2 | decrease by 4 | Stopped by <br> paper |
| Beta- <br> e- emission | $\beta-$ <br> electron | -1 | 0 | increase by 1 | 0 | Aluminum Foil |
| Beta+ <br> e- capture | $\beta+$ <br> Positron | +1 | 0 | decrease by 1 | 0 | Aluminum Foil |
| Gamma | $\gamma$ | none | none | none | none | Lead |

The net result of $\alpha, \beta$ - or $\beta+$ decay is a new element. In $b-$ decay, a neutron decays into a $p+$ and an ewhich is then ejected. In $\beta+$ decay a p+ captures an e- and transforms into a neutron. But despite the nature of the reaction the law of conservation of matter still applies and the equations are balanced the same way. Note $\alpha$ particle is a helium nucleus!

Another type of reaction occurs when something impacts a nucleus. These reactions result either in the nucleus splitting (fission) or the combination of two or more nuclei to form a third, different nucleus (fusion).

Balancing Nuclear Equations: Matter must be conserved including all p+\&n. Example:
